CHAPTER 10

The first part of the chapter discusses the importance of maintaining accurate records of all transactions. This is essential for the proper functioning of the business and for the protection of the interests of the owners and creditors. The second part of the chapter discusses the various methods of accounting, including the double-entry system, which is the most widely used method. The third part of the chapter discusses the various types of accounts, including assets, liabilities, and equity accounts. The fourth part of the chapter discusses the various types of financial statements, including the balance sheet, the income statement, and the statement of cash flows. The fifth part of the chapter discusses the various types of taxes, including income tax, sales tax, and property tax. The sixth part of the chapter discusses the various types of insurance, including life insurance, health insurance, and fire insurance. The seventh part of the chapter discusses the various types of investments, including stocks, bonds, and real estate. The eighth part of the chapter discusses the various types of contracts, including sales contracts, lease contracts, and employment contracts. The ninth part of the chapter discusses the various types of legal entities, including sole proprietorships, partnerships, and corporations. The tenth part of the chapter discusses the various types of legal disputes, including contract disputes, tort disputes, and real estate disputes.

FOREWORD

The Pond Dynamics/Aquaculture Collaborative Research Support Program (PD/A CRSP) represents an international community of researchers and institutions dedicated to strengthening health and nutrition in developing countries by improving the efficiency of pond aquaculture systems. It is one of several agricultural CRSPs supported by the U.S. Agency for International Development under the authority of Title XII of the International Development and Food Assistance Act of 1975.

The "Global Experiment" in Pond Dynamics/Aquaculture is the major CRSP research activity, covering the period from 1982 to 1987. The Global Experiment was designed to quantitatively describe the physical, chemical and biological principles of pond culture systems. The information gained from the Global Experiment will be used to improve production technologies and develop quantitative production functions to facilitate rigorous economic analyses of aquaculture systems.

Standardization is a key element of the Global Experiment. Standardization permits the comparison of data from diverse geographic locations. The experimental design involves monitoring specified environmental and fish production variables in accordance with standardized work plans in twelve or more ponds at each of seven geographical locations. The variables observed, frequency of observation, and materials and methods are uniform for all locations. The field data are filed in a centralized data base, called the CRSP Central Data Base. Statistical methods will be used to test hypotheses about correlations between variables and to evaluate the sources of variance within ponds, between ponds within locations, and between locations.

The CRSP Central Data Base will be used to develop predictive models of the processes occurring in pond culture systems. The models will be used to provide guidance for ongoing and future research, to predict the performance of existing and proposed pond systems subject to specific inputs and constraints, and to improve the operation and efficiency of pond culture systems.

The Global Experiment includes three cycles of experiments. Each cycle consists of two series of observations, one during the dry season and one during the wet season. The objective of the first cycle is to create a detailed baseline of chemical, physical, and biological data on all ponds treated with a standard level of inorganic fertilizer. In the second experimental cycle, ponds treated with inorganic fertilizer are compared to ponds treated with organic fertilizer. In the third cycle, the responses of ponds to different levels of organic fertilizer are compared.

The goal of the Pond Dynamics/Aquaculture Collaborative Research Data Reports (referred to as Data Reports) is to record the CRSP Central Data Base and to present interpretations of site specific results. The Pond Dynamics/Aquaculture CRSP has conducted the Global Experiment at seven project sites in six developing countries: Thailand, Indonesia, the Philippines, Panama, Honduras, and Rwanda. The first volume of these reports provides descriptive information for each CRSP site. It presents the physical characteristics of each site, including a geographical sketch, climatology, and water and soil analyses. Experimental cycles are described in CRSP Work Plans One to Three, which are summarized in the first volume.

Volume One will serve as the reference volume for the entire report series. Subsequent volumes will focus on each site separately. Each Data Report will include one cycle (wet and dry seasons) of the Pond Dynamics/Aquaculture CRSP Global Experiment. Therefore, with few exceptions, each project site will have three Data Reports devoted to it, representing the results of the three cycles of the Global Experiment. In addition to the hard copy of experimental data published as a part of each Data Report, data are also available from the PD/A CRSP in electronic form (on diskette) for computer analysis. Cycle I of the Global Experiment at the Brackishwater Aquaculture Center (BAC) in Iloilo, Philippines is presented in this volume.

INTRODUCTION

The goal of Cycle I of the Pond Dynamics/Aquaculture CRSP experiments was to characterize and quantify the properties, ecosystem dynamics, and fish production performance of earthen ponds under similar management protocols (low nutrient inputs) at several tropical sites worldwide. Pond culture trials were conducted during both wet and dry seasons.

This report presents the results of work performed during Cycle I of the PD/A CRSP at the Brackishwater Aquaculture Center (BAC), College of Fisheries, University of the Philippines in the Visayas (UPV), as a collaborative effort among personnel from UPV and the University of Hawaii during 1983 and 1984. The data collected during these experiments were transmitted to the CRSP Program Management Office for inclusion in the Central Data Base. The text of this report is being prepared long after the fact by referring to the data and to lengthy technical reports submitted previously, from which some text, tables, and figures have been taken.

The BAC is located about 17 km north of Iloilo City on the island of Panay. The facility is described in Volume One of this Data Report series (Egna et al. 1987). Eighteen earthen ponds of 0.1 ha surface area were used for these experiments.

MATERIALS AND METHODS

This work was conducted according to the CRSP First Work Plan (PD/A CRSP undated) insofar as possible. During both the rainy season (June-December 1983) and dry season (February-July 1984) trials, eighteen 0.1-ha ponds were stocked with either *Oreochromis niloticus* (Nile tilapia) or *Chanos chanos* (milkfish). Tilapia fingerlings of 10-13 g individual weight were stocked at 5000 fish/ha in each of six ponds (three ponds were 0.6 m deep and three were 0.3 m deep) during each season; milkfish fingerlings weighing 2-4 grams each were stocked at 3000 fish/ha in each of twelve ponds (six ponds at each of the two depths) during each season. Tilapia were acclimated to saltwater over a period of one week before stocking. Milkfish fingerlings were stocked directly.

Pond bottoms were prepared before the experiment by excavating to the original bottom level, drying for 10 days, liming at 2 T/ha, and fertilizing with chicken manure at 4 T/ha. The deeper ponds ("phytoplankton ponds") were then filled completely to 60 cm as soon as possible to foster phytoplankton blooms. The shallow ponds ("lablab ponds") were initially filled to about 10 cm to foster the development of lablab, then filled to 30 cm. All ponds were stocked simultaneously. Every 15 days during the trials 25 kg/ha of inorganic fertilizer (16-20-0) was added to the ponds.

Numerous small departures from the Experimental Protocol took place because Work Plan I was not available at the time this experiment began, and because some of the suggested procedures could not be performed at the BAC. In order to allow readers to compare this work with that from other CRSP sites, Appendix A lists the actual methods used at the BAC during Cycle I, and is followed by a summary of departures from the protocol.

Fish growth was monitored monthly. Tilapia growth was monitored by cast net samples; milkfish growth was usually monitored by trapping, although cast net samples were taken on three dates for comparison. The ponds were completely drained and the fish were harvested after approximately five months.

RESULTS

Wet Season

Weather

The Cycle I wet season followed an unusually severe eight-month drought. The general weather condition was recorded as "fair" on 72% of the days of this experiment, whereas the remainder were "overcast" or "slightly overcast." Rainfall totaled 117.1 cm for the period, with a maximum of 7.5 cm for a single 24-hour period, and typical monthly totals of about 30 cm. Relative humidity readings averaged 84.5%.

Daytime air temperatures ranged from about 25 to 33°C, with no observable trends for the period except for lower temperatures in November. Wind speed averaged about 10 km/h, with a maximum near 30 km/h; 65% of wind direction observations were between SSW (210°) and NNW (330°).

Soil

Soil pH increased from neutral to slightly alkaline during the experiment. The coefficient of variation for the four sample dates was 7.5%. Organic matter content ranged from 2.5 to 3%, whereas total nitrogen was always less than 0.1%; no temporal trend was apparent in either measure.

Soil phosphorus contents exhibited high variability, such that few sampling periods could be distinguished statistically. Phosphorus levels were higher after the manure treatment, with values of 20-70 ppm. Exchangeable iron was generally below 1400 ppm and aluminum was undetectable.

Ponds and Pond Water

Physical and Chemical Properties. The nominal depth for the six phytoplankton ponds was 60 cm, but actual depths maintained were 40-50 cm. The 12 lablab ponds were nominally 30 cm deep and were maintained at 25-30 cm.

Dissolved oxygen (DO) exhibited typical diel cycles in all ponds, with early morning concentrations lower in the lablab ponds than in the phytoplankton ponds. Daily mean water temperatures ranged from 23 to 38°C; diel cycles reached wider extremes in lablab ponds than in phytoplankton ponds. Ponds were usually well-mixed vertically, but showed stratification on some dates.

As was observed for soil pH, pond water pH showed a significant increasing trend for the period; the two pond types did not show significant differences.

Salinity ranged from 16 to 33 ppt; lablab ponds were more variable than phytoplankton ponds.

Average ammonia concentrations ranged mostly from 0.025 to 0.070 mg/L; the two pond types did not differ significantly. Total phosphorus concentrations ranged mostly between about 0.350 and 0.800 mg/L; reactive P ranged mostly from 0.100 to 0.525 mg/L. Nitrate and nitrite levels were generally low, with large coefficients of variation.

Biological Characteristics. Secchi disk depths were always greater than 19 cm; it appears that lablab ponds were generally more turbid than phytoplankton ponds. Chlorophyll *a* increased rapidly at first, then declined, then held steady for some weeks.

Phytoplankton genera present commonly included *Navicula*, *Oscillatoria*, *Chlorella*, *Amphora*, and *Nitzschia*. Diversity appeared to decrease during the period, with only *Navicula* appearing consistently in later months. Copepods were the most common zooplankton; however, some sampling dates showed no zooplankton, particularly toward the end of the period.

Fish Production. Tilapia grew from initial mean weights of 10-13 g to final weights of 112-148 g in phytoplankton ponds, and to final weights ranging from 116-257 g in lablab ponds in 141 days. Growth patterns appeared to be linear; average daily weight increments in the two pond types were 0.9 and 1.1 g/day, respectively. Tilapia survival averaged 57%.

Milkfish grew from approximately 2.5 g/fish to 57-129 g/fish in phytoplankton ponds, and to 128-308 g/fish in lablab ponds in 149 days. Growth appeared to decrease or cease during the last month; average daily gains in phytoplankton ponds and lablab ponds were 0.7 and 1.4 g/day, respectively. Milkfish survival averaged 91%.

Dry Season

Weather

The general weather condition was recorded as "fair" on 93% of the days when it was determined, the remainder being "overcast" or "slightly overcast." Daily solar radiation was highly variable, as shown in Figure 1. Rainfall totaled 41.7 cm for the period, with a maximum of 6.1 cm for a single 24-hour period (Figure 2). Relative humidity readings averaged 78.8%.

Daytime air temperatures ranged from about 23-37°C, with little apparent trend for the period except that temperatures were lower in June (Figure 3). Wind speed averaged about 7 km/h, with a maximum near 30 km/h (Figure 4); 39% of the wind direction observations were NNW (330°).

Soil

Soil phosphorus content exhibited high variability, as was true in the wet season, and decreased during the growout period. Concentrations ranged from 20-45 ppm. Exchangeable iron was below 1400 ppm, as was true in the wet season; aluminum, similarly, was undetectable.

Ponds and Pond Water

Physical and Chemical Properties. The nominal depth for the six phytoplankton ponds was 60 cm; actual depths maintained were less, but approached 60 cm in the latter part of the period (Figure 5). The 12 lablab ponds were nominally 30 cm deep, and were maintained at 25-30 cm.

Dissolved oxygen (DO) exhibited typical diel cycles in all ponds, with early morning readings being lower in the lablab ponds (Figure 6). Water temperatures ranged from 22.5 to 42.0°C (Figures 7 and 8); diel cycles reached greater extremes in lablab ponds than in phytoplankton ponds. Ponds were usually well-mixed vertically, but showed stratification on some dates.

Pond water pH ranged from 7.6 to 8.9, except for a two-week period of lower values. Salinity ranged from 8 to 48 ppt.

Ammonia concentrations were higher and more variable among ponds than they were in the wet season, with a maximum average value of 0.300 mg/L (Figure 9). Total phosphorus ranged from about 0.400 to 1.000 mg/L, with a decreasing trend through the period (Figure 10). Nitrate and nitrite levels were generally low, with large coefficients of variation (Figure 11).

Biological Characteristics. Secchi disk depths were always greater than 30 cm in phytoplankton ponds (Figure 12). The bottom was nearly always visible in lablab ponds, so readings were not recorded. Chlorophyll *a* concentrations ranged from 0 to 25 mg/m³ (Figure 13); the two pond types did not differ significantly.

Phytoplankton counts showed no differences between pond types, and were always fewer than 200 cells/ml.

The two pond types showed similar ranges of DO production rates over the period (Figure 14). Phytoplankton ponds exhibited rates of 2 to 18 g O₂/m²/day and biomass levels of 20 to 104 g/m², and lablab ponds exhibited DO rates of 5 to 22 g O₂/m²/day and biomass levels of 52 to 102 g/m².

Fish Production. Tilapia grew from initial mean weights of 11.4-14.7 g to final weights of 46-163 g in phytoplankton ponds (Figure 15), and to 107-254 g in lablab ponds (Figure 16). Growth was similar in the two pond types, and decreased dramatically during the last two months. Average daily weight increments ranged from 0.23 to 1.71 g/day in phytoplankton ponds and from 0.65-1.61 g/day in lablab ponds. Tilapia survival averaged 47% in phytoplankton ponds and 71% in lablab ponds.

Milkfish grew from approximately 9.3-13.5 g/fish to 66-84 g/fish in phytoplankton ponds (Figure 17), and to 72-384 g/fish in lablab ponds (Figure 18). Growth appeared to decrease or cease during the last two months, as it did for tilapia; daily gains in phytoplankton ponds were 0.55-1.20 g/day, and 1.83-3.20 g/day in lablab ponds. Milkfish survival averaged 89.4%.

DISCUSSION

Although ponds exhibited considerable variation in many characteristics, including fish production, the data set is reasonably complete, and thus serves as baseline information for comparison with future experiments.

The pond pretreatment was apparently successful in keeping the soil pH in the alkaline range. However the phytoplankton ponds were poorly sealed, a condition which was not corrected until the second half of the dry season experiment.

Water properties and biological characteristics of the pond ecosystems exhibited few surprising values. There was an apparent relationship between soil fertility and fish production, in that ponds with higher levels of soil phosphorus produced more oxygen, and oxygen production, in turn, was related to fish growth.

APPENDIX A

Methods used during Cycle I of the Pond Dynamics/ Aquaculture CRSP in Iloilo, Philippines

METHODS

Meteorological Observations

All weather data taken at about 0830 hours and 1530 hours every weekday on the dike between the ponds throughout the grow-out period. Half-way through this experiment, a continuous reading Licor integrating photometer became available and was used from that time for solar radiation readings. The gap from March 9 to April 16 resulted from lack of coverage for absent personnel.

1. General weather conditions

The daily weather conditions were characterized twice daily as fair (F), slight overcast (SO) or overcast (O).

2. Wind speed and direction

Wind speed was measured with Bacharach Style 3035 A anemometer in miles per hour. Wind direction was noted from a wind vane placed on a dike between two of the ponds and aligned with magnetic north.

3. Air temperature

Air temperature was measured initially on an ordinary mercury thermometer accurate to 0.1°C. Later a min-max thermometer was installed for daily weekday readings of overnight minimum temperature, daytime maximum temperature and two temperatures at recording time.

4. Solar radiation

Light intensity was measured with a Takimura Electric Works Horticultural Luxmeter, model # DM-28 in lux until March 20, 1984, at which time the LI-COR photometer was installed and became operational on April 16, 1984. Solar radiation was the sum of the hourly recordings during each day.

5. Evaporative potential

An evaporation pan was constructed to float in one of the ponds (B2). The pan was 24" in diameter, 6" deep and painted a medium brown. The pan was placed in a circular hole cut in a 3' x 3' x 4" piece of styrofoam for flotation. Water from the pond was placed in the pan and changes in the water level inside the pan were recorded in the afternoon. Improvements in this method are necessary.

6. Relative humidity

Relative humidity was measured with a sling psychrometer made by Taylor Instrument Company, Rochester, New York. Readings were discontinued on May 8, 1984, when the psychrometer thermometer was broken.

7. Rainfall

Accumulated rain was measured in inches with a Tru Check Rain Gauge and recorded most weekdays and later converted to centimeters.

8. Barometric pressure

A Sargent-Welch Scientific Company barometer was used to measure air pressure most weekdays.

Soil Chemical Analyses

Soil samples for analysis were a composite of soil from eleven locations in each pond. The overlying organic and lablab layers were scraped away and the top 5 cm of soil taken as the sample. These samples were taken before the chicken manure was applied at the beginning, two weeks after manure application, and monthly thereafter, until just before draining at the end of the experiment.

1. Wet pH

The samples were mixed thoroughly in plastic bag and the pH measured with a standardized Corning pH meter.

2. 1:1 pH

After air drying, the samples were ground and passed through a #20 (850 micrometers) sieve. Twenty (20) grams per sample were weighed out with a triple beam balance and then mixed with 20 ml of distilled water (ratio 1:1). The mixture was agitated on a shaker for 30 minutes, after which the pH was measured with a standardized Corning pH meter.

3. Total nitrogen

Total nitrogen was assayed according to the procedure by Dewis and Freitas (1965).

4. Available phosphorous

The sodium bicarbonate extraction method described by Olsen in Blank and Walkley (1965) was used. The filtrate was prepared with an acid pretreatment before determining available phosphorous according to Strickland and Parsons (1982).

5. Organic matter

A method modified from Black and Walkley (1965) for determining organic matter content was used.

6. Exchangeable Fe

A procedure modified from Black and Walkley (1965) was used for measuring exchangeable iron.

7. Exchangeable Al

A procedure modified from Black and Walkley (1965) was used for measuring exchangeable aluminum.

Water Physical Measurements

1. Dissolved Oxygen

Dissolved oxygen (DO) was measured around 4:30 a.m. and 3:30 p.m. in all 18 ponds on Mondays, Wednesdays, and Fridays of every week with a YSI model 51B oxygen meter about 10 cm from the surface and near the bottom. One additional measurement was taken around 3:30 p.m. on every other Tuesday to give three DO readings from which to calculate the approximate oxygen production of all photosynthetic organisms in the ponds (McConnell, 1962). The meter was calibrated against atmospheric oxygen for 15 minutes each time before the first reading. Chlorinity was converted from the salinity readings for corrections.

2. Water temperature

Water temperature was measured at 4:30 a.m. and 3:30 p.m. in all 18 ponds on Mondays, Wednesdays, and Fridays with the thermometer of the YSI 30 meter during the DO measurements, 10 cm from the surface and near the bottom.

3. Salinity

Salinity was measured at 4:30 a.m. and 3:30 p.m. on Mondays, Wednesdays, and Fridays, and at 9:00 a.m. on Tuesdays and Thursdays in all 18 ponds, using an Atago refractometer. Salinity was measured 10 cm from surface and near the bottom. A modified Van Dorn type sampler was used to collect the bottom water sample.

4. pH

pH readings were taken twice a month from the same places as top and bottom DO around 4:30 a.m. with a Corning pH meter, standardized before each set of readings.

5. Pond depth

Water levels in each pond were measured and recorded by means of depth gauges calibrated in cm installed near the inlet gate. Depths were recorded in the afternoon every weekday.

Water Chemical Analyses

Five hundred (500) ml water samples were taken from composite water samples collected 10 cm from the top and 10 cm from the bottom in several places in each of the 18 ponds. Selected parameters were analyzed. These samples were taken in the morning at monthly intervals at first, and before draining and after flooding, which occurred every two weeks during the grow-out period. After May 3, 1984, analyses were immediately made in the following order: ammonia, nitrite, reactive P, total P, and nitrate (the last two simultaneously).

1. Nitrate

The sodium salicylate method as described in Singh (1978) was used.

2. Nitrite

The procedure described by Strickland and Parsons (1972) (pages 77-80) was used.

3. Ammonia

The procedure described in Strickland and Parsons (1972) (pages 87-89) was used.

4. Reactive Phosphorus

The procedure described by Strickland and Parsons (1972) (pages 57-62) was used.

Food Organism Production

1. Secchi disk depths

A standard 8" diameter Secchi disk was used daily on weekdays at 9:00 a.m. to measure the light penetration in all 18 ponds. Occasionally it was necessary to go to the opposite end of the pond to avoid floating lablab or lumut. The visibility in the lablab ponds was mostly to the bottom, but bottom visibility was not specifically recorded.

2. Chlorophyll

Chlorophyll samples taken from the same composite water samples as the water chemical analyses. These were also measured just before draining and just after flooding every two weeks after May 3, 1984. Pigments were extracted according to the method by Olsen and measurements taken on a Bausch and Lomb Spectrophotometer (model 70). Calculations for chlorophyll *a*, *b*, and *c* were according to the techniques described by Lind (1977) (pages 129-134).

3. Plankton samples

Water samples for plankton studies were taken from the same composite water samples as the water chemical analyses and were taken every week just before draining and just after flooding after May 2, 1984. The plankton were concentrated into two liters from the composite samples through a #110 mesh phytoplankton net. After washing down all of the material collected on the netting and collecting it in small jars, the material was placed in a test tube and further concentrated by centrifugation for 30 minutes at a speed that did not rupture the cells. The final sample volume which included some water was 10 ml. A hemacytometer was filled from this sample. Microscopic examination was performed with a binocular, compound microscope. Unicellular organisms and colonies were each counted as one. Plankton genera were counted and calculations made exactly in accordance with the method described by Martinez, et al. (1975).

4. Community Respiration

Every two weeks on the Tuesday evening before the regular dissolved oxygen measurements, an extra set of readings were taken. This plus the morning and afternoon readings of the following day (Wednesday) were used to calculate the total oxygen evolved in the ponds over that twenty-four hour period. The basic formula is provided by Olah et al. (1978). These measurements were begun in late September 1983. The graph of community respiration is labeled "oxygen production."

5. Lablab standing crop and composition

Nine (9) sediment core samples were taken biweekly in a z-shaped pattern from each pond. These were composited and a portion taken for assessing generic composition. The remaining portion was weighed, oven dried (moisture-free) and weighed again for biomass.

The portion to be assayed for generic composition was mixed with a small amount of water from the ponds. Three drops of the mixture were then put on regular laboratory slides one at a time and covered with a 20 x 20 mm cover slip. The preparations from each drop were surveyed and the species noted and counted along 5 to 10 transects across the slide. The genera found were ranked according to abundance. These assays were performed twice each month.

Fish Production

1. Growth

a. Milkfish

Growth was monitored monthly. For milkfish, two sampling methods were employed. The standard method is called the "pasulang" method. It involves constructing a bamboo trap in a "funnel" configuration at the gates, and allowing water to flow through the trap into a partially drained pond.

Milkfish swim against the current, and hence into the trap. The fish can then be easily scooped from the trap for measurement. Thirty fish were weighed *en masse* and returned to the pond.

The other method, which was used as a check against the pasulang method, was to use a fine-mesh cast net. To minimize disturbance of the pond bottom, especially in the lablab ponds, the number of casts was limited to ten. The water level was lowered so that the workers could locate and catch the fish easier. This method was used only during the first, third, and last samplings.

b. Tilapia

Tilapia growth was also sampled monthly, but only the cast net method was used. As with the milkfish, the water level was lowered and up to ten casts were performed to obtain the ten percent population sample. The fish were measured *en masse* and returned to the ponds.

2. Harvest

Both the milkfish and tilapia were harvested on July 3, 1984, after each was regularly sampled as described above. The ponds were drained and all of the fish remaining after sampling were collected by hand. The total number was counted and a total weight was taken. A 10% subsample was taken for individual lengths and weights.

3. Survival

Mortalities were recorded during the grow-out period when fish were observed on the pond surface or the bank. The dead were then removed.

DEPARTURES FROM THE EXPERIMENTAL PROTOCOL

Numerous small departures occurred in this experiment because the Experimental Guidelines were not available at the time of implementation. Some of the suggestions were also not appropriate for the situation at BAC. The departures and problems are listed below with short explanations. The page numbers in Work Plan I on which the original guidelines are found are given in parentheses.

1. One thousand m² ponds were used instead of 400 to 500 m² ponds (pg. 3). The five hundred m² ponds at BAC were not available.
2. 16-20-0 fertilizer at 50 kg/ha/month was applied instead of superphosphate at 8 kg/ha/month (pg. 3). Superphosphate was difficult to obtain at this site.
3. *Oreochromis niloticus* were stocked at 10 grams instead of 25-50 grams (pg. 3) and 5000/ha instead of 10,000/ha (pg. 3) or 2000/ha (pg. 11). The fish were ready to stock at 10 grams and we were aware of the stocking rate given in the Work Plan; however, BAC experts felt that 10,000/ha was too high and 2000/ha was too low for local conditions.
4. Alkalinity, total hardness, and orthophosphate were not measured (pg. 4). The first two are not usually problems in brackishwater.
5. Reproduction was not determined (pg. 4). Nile tilapia reportedly does not reproduce in brackishwater above 15 ppt. Milkfish does not mature within the culture period chosen.
6. Light was not measured with a LI-COR meter (pg. 5). A LI-COR meter was not available.
7. Max-min thermometers were not used for measuring temperature (pg. 4). We overlooked this one.
8. Pond morphology was not mapped (pg. 5). The site is flat with few distinctive morphological characteristics.
9. Dissolved oxygen and temperature were not taken 25 cm from the top and bottom of the pond water (pg. 5-6), but rather 10 cm from top and bottom. The suggested depths would result in only one reading from the middle of a 50-cm pond.
10. Pond depth was read to the nearest cm instead of 0.5 cm (pg. 60). One-cm spacings were chosen for convenience.
11. Water budgets were not determined (pg. 6). Determining water budgets in tidal-fed ponds is somewhat complex and we have not gotten around to this one yet.
12. Diurnal studies were only done once (pg. 6). We just did not get around to doing this one.

13. The metals were not done in water quality analyses (pg. 7). We relied on the water chemistry traditionally done at BAC.

14. Top and bottom water samples were mixed instead of using 90-cm columns of water (pg. 6-8). We used the traditional sampling tools available at the BAC.

15. Fish were not sexed at stocking (pg. 9). See #5.

16. Secchi disk visibility was taken at only one location (pg. 9). We overlooked this one.

17. Chicken manure was spread on the surface of the pond bottom at 4 tons/ha irrespective of the organic matter content of the soil (pg. 10). This method is traditionally used on Panay Island. Mixing the manure into the surface soil requires extra work.

18. Data loggers were not installed during the experiment (pg. 11). These units were not available in time for the experiment.

19. A prophylactic application of lime was made at a rate of 2 tons/ha (pg. A-3). This application is typically used when lime requirements are not measured.

20. Fertilizer was broadcast rather than placed in a dissolving bag (pg. A-4). See Materials and Methods.

21. Those ponds with more than 10% mortality were not eliminated as replicates (pg. A-4). Tilapia mortality usually exceeds 10%.

22. Soil exchangeable bases, total exchangeable acidity, carbonate, zinc, copper, and manganese were not determined (pg. D-3). The parameters measured were considered most important and were already a significant work load for the research assistants.

23. The LI-COR photometer only became available midway through this experiment. The luxmeter and the LI-COR meter data were graphed side-by-side but not connected because the values are not easily interchangeable.

24. A max-min thermometer was installed at the ponds. The data were inconsistently taken, but were available at BAC. We decided to include and present daily average air temperatures for comparison with the rainy season air temperature data.

25. The pond morphology was not mapped in detail (editor's note: Pond morphology data were obtained at a later date, and are included in Appendix B.).

26. Dissolved oxygen was taken only near the top, because experience has shown that in these shallow ponds (phytoplankton ponds--60 cm deep), the top and bottom dissolved oxygen readings were only very rarely different.

27. Top and bottom water samples were not taken due to the shallowness of the ponds.

28. The problem of measuring evaporative potential was a difficult one which we never satisfactorily solved.

29. Diurnal studies were done, but not reported here.

APPENDIX B

Complete Set of Data from Cycle I of the Pond Dynamics/ Aquaculture CRSP in Iloilo, Philippines

Units of Measurement and Abbreviations Used in the Appendix Tables

Daily Weather Measurements:

SOLAR1 (solar radiation)	E/m ² /d
SOLAR2 (solar radiation)	cal/cm ² /d
RAIN (rainfall)	cm/d
WIND (wind speed)	km/hr
ATEMPMAX (max air temperature)	°C
ATEMPMIN (min air temperature)	°C
EVAP (evaporation)	mm/d

Daily Pond Measurements:

DEPTH	m
INFLOW	m ³ /hr
OVERFLOW	Y/N
"cha"	<i>Chanos chanos</i>
"nil"	<i>Oreochromis niloticus</i>
SALINITY	ppt

Intensive Sampling Measurements:

All DO (dissolved oxygen)	mg/L
All TEMP (temperature)	°C
ALKA (alkalinity)	mg/L (as CaCO ₃)
HARD (total hardness)	mg/L (as CaCO ₃)
All N (Kjeldahl, NO ₂ , NO ₃ , Total)	mg/L
All P (Total, Ortho-PO ₄)	mg/L
SECCHI DISK	cm
CHLOROPHYLL a, b, or c	mg/m ³

Diurnal Measurements:

All DO (dissolved oxygen)	mg/L
All TEMP (temperature)	°C

Fish/Shrimp Stocking, Sampling, and Harvesting:

"STK"	stocking
"SAM"	sampling
"HAR"	harvesting
"cha"	<i>Chanos chanos</i>
"nil"	<i>Oreochromis niloticus</i>
POP. WEIGHT	kg
SAMPLE LENGTH	cm
REPROD. WEIGHT	kg

Plankton and Benthos:

NET (PRIMARY) PRODUCTION	mg C/m ³ /d
GROSS (PRIMARY) PRODUCTION	mg C/m ³ /d

Water Quality Characteristics:

ALKALIN (alkalinity).....	mg/L (as CaCO ₃)
HARDNESS	mg/L (as CaCO ₃)
All N (NH ₃ , NO ₂ , NO ₃ , NO ₂ +NO ₃)	mg/L
All P (Total, Ortho-P)	mg/L
Cl ⁻	mg/L
SALT	ppt
SO ₄	mg/L
BORON	mg/L
CALCIUM.....	mg/L
COPPER	mg/L
IRON.....	mg/L
MAGNESIUM	mg/L
POTASSIUM.....	mg/L
SODIUM.....	mg/L
ZINC.....	mg/L

Pond Soil Characteristics:

CLAY	%
SILT	%
SAND	%
ORGANIC MATTER	%
SOIL-P.....	ppm
SOIL Ca	meq/100g
SOIL Mg.....	meq/100g
SOIL K	ppm
SOIL Na.....	meq/100g
SOIL N.....	%
SOIL NH ₄	ppm
SOIL NO ₃	ppm
SOIL CEC.....	meq/100g
SOIL SALT	mmhos/cm
SOIL Al.....	ppm
SOIL Fe.....	ppm
SOIL Zn.....	ppm
SOIL Mn.....	ppm
SOIL Cu	ppm
SOIL SO ₄	ppm

Pond Morphometrics:

AREA	m ²
VOLUME	m ³

Analysis of Nutrients and Lime:

All NUTRIENTS	% (dry matter basis)
---------------------	----------------------

Nutrient and Lime Inputs:

All QUANTITIES	kg/ha
CHICK	chicken manure
I16200.....	16-20-0
TSP	"triple superphosphate"
"cac"	CaCO ₃
